Imprimis IVF & Fertility Centre
2nd Floor, SR Plaza, Hyderpora Chowk, Hyderpora, Srinagar-190014

Srinagar, Jammu and Kashmir Jan 23, 2023 (Issuewire.com) - In today's words full of health problems, infertility became a very common problem among parents. Most people don't know that for many couples struggling with infertility or for whom traditional conception and pregnancy are not an

option, such as same-sex couples or infertile women, diagnoses that make it impossible to find sperm and egg are not fertile. IVF may be the first and most successful option. The best feeling out there is knowing you're going to be a father. This is made possible by Imprimis, the [best IVF center in Srinagar](#); Our guiding thought is to maximize results and minimize costs. Our comprehensive and detailed method will speed up and reduce the stress of treating an infertile couple. To schedule a meeting today.

We offer the following IVF treatments in Srinagar;

Infertility Tests

[Infertility Tests](#) are the process by which fertility is generally assessed to identify the "fertile window" in the menstrual cycle known as fertility testing. Fertility is affected by general health, and STI testing is a related important area of study. From puberty to menopause, healthy women are fertile, although fertility usually declines significantly towards the end of this period. Menarche and the existence of secondary sex characteristics, such as breast development, pubic hair development, and changes in body fat distribution, are commonly used to determine the onset of puberty. Because fertility declines to the point where it is highly impossible to produce a viable pregnancy, fertility often ceases before menopause.

Sperm and genetic testing are done during male fertility testing to check for other issues, such as impotence. Sperm count, motility, morphology, volume, fructose concentration, and many other activities can be examined in semen. Retrograde ejaculation and undescended testicles are also reviewed along with medical history, including cancer treatment, radiation exposure, drug use, etc.

It's important to know if infertility is to blame. Accordingly, we perform a blood test to determine your hormone levels and an ultrasound to examine your uterus and ovaries for analysis.

IUI therapy

[IUI therapy](#) is an artificial technique which is called intrauterine insemination and is used in the treatment of infertility. When your ovary produces one or more eggs for fertilization, the clean, concentrated sperm is inserted directly into the uterus. The result expected from this is for the sperm to get inside the fallopian tubes, fertilize a mature egg, and make a pregnancy. Depending on the underlying cause of infertility, IUI may be timed to coincide with your regular cycle or with fertility drugs. In an IUI, our expert IVF doctor injects sperm into the uterus of a mother at the time of ovulation.

IVF procedure

The full form of IVF is In vitro fertilization. One of the best-known applications of assisted reproductive technologies (ART) is as follows. In the treatment of vitro fertilization, doctors use a mixture of drugs and surgical techniques to help the sperm to fertilize an egg and place that mature egg in the uterus. Get the best [IVF treatment in Srinagar](#) with **Imprimis IVF and Fertility Centre**.

First, you take a drug that matures, and many of your eggs are ready for fertilization. Then the eggs are taken out from the mother's body and mixed with the sperm in the laboratory. They then place one or more fertilized eggs (embryos) in your uterus. Pregnancy occurs if some of the embryos implant in the formation of the uterus. In this process, mature eggs are taken out from the ovaries and the remaining process is done in a special petri dish to make zygotes.

ICSI therapy

IVF can fertilize an egg in two different ways: traditional and ICSI. Eggs are placed near 50,000 or more free-swimming sperm in a laboratory dish during conventional IVF. When any of the sperm comes inside the cytoplasm of an egg, the fertilization process happens. In [ICSI treatment](#), an individual sperm is inserted in an egg with the help of a small needle. After fertilizing through IVF or ICSI, the egg grows in the lab for almost 7 days before being implanted in the woman's womb. This method allows us to simulate the process by which sperm enters a mature egg in a woman's uterus and fertilizes it by inserting sperm into the egg.

Transfer and culture of blastocysts

The term "[blastocyst culture](#)" refers to embryos grown for an additional two days in the laboratory, after which they are called blastocyst embryos. Blastocyst transfer refers to the placement of blastocyst embryos into the woman's uterus on day five in the same way as day three embryos.

In this process, an egg and a sperm are combined, and the embryo develops in 4 to 6 days in a laboratory. We can ensure the safety of your pregnancy by using an embryo for blastocyst culture and transfer.
