

FDP Mold Remediation Advises Early Moisture Checks as Spring Humidity Levels Begin to Rise

Early moisture checks can help property owners reduce mold-related issues before peak humidity arrives

Washington, D.C, District of Columbia Mar 30, 2026 (Issuewire.com) - FDP Mold Remediation is encouraging property owners and managers to evaluate indoor moisture conditions ahead of the spring season, as rising humidity and changing weather patterns can create conditions that support mold growth in residential and multi-unit properties.

As temperatures increase, indoor environments may begin to retain moisture from condensation, minor leaks, and reduced airflow in enclosed spaces. Areas such as basements, crawl spaces, utility rooms, and wall cavities are commonly affected, particularly in buildings with older construction or limited

ventilation.

The company notes that mold-related issues are often linked to persistent moisture rather than a single event. Seasonal transitions can make underlying moisture conditions more noticeable, especially in properties where small leaks or ventilation limitations have gone unaddressed during colder months.

“Seasonal humidity changes can expose existing moisture issues that may not be visible during colder months,” said Jose Calderon, mold remediation specialist with FDP Mold Remediation. “Reviewing ventilation and addressing minor moisture sources early can help reduce the likelihood of larger remediation needs later.”

FDP Mold Remediation recommends that property owners and managers take several practical steps before peak humidity levels arrive to prevent mold growth:

- Check basements, storage areas, and crawl spaces for dampness.
- Review airflow and ventilation in enclosed or low-traffic areas.
- Address minor plumbing or roof leaks.
- Monitor surfaces where condensation is likely to occur.

These steps are intended to help identify moisture-related conditions early and reduce the likelihood of more extensive remediation work later.

The advisory is particularly relevant for multifamily buildings and rental properties, where moisture conditions in one unit or shared structure can affect adjacent areas. Early review and coordination may help property managers address issues before they expand across multiple units.
